## 1. What Is Tramadol and Why Is It Prescribed?

Tramadol is a prescription pain medication used to treat **moderate to moderately severe pain**. It is often prescribed after surgery, injury, or for chronic pain conditions when non-opioid medications are not effective enough.

Tramadol works on the central nervous system to reduce the sensation of pain, helping patients manage daily activities more comfortably. However, because it affects brain chemistry, it must be used carefully under a doctor's supervision.

## 2. How Tramadol Works for Pain Relief

Tramadol works in two main ways:

- It binds to opioid receptors in the brain to reduce pain signals.
- It increases serotonin and norepinephrine levels, which also help in pain modulation.

This dual mechanism makes it effective for different types of pain, including nerve-related discomfort.

## 3. The Importance of Medical Supervision

Tramadol should only be used under a licensed healthcare provider's guidance because:
